Machine Learning Exercise Sheet 8
Deep Learning II

In-class Exercise

See the recording of the in-class exercise for the discussion of the code in the notebook.

Problem 1: See notebook `exercise_inclass_08_pytorch.ipynb` on Moodle.

Homework

Problem 2: You are trying to solve a regression task and you want to choose between two approaches:

1. A simple linear regression model.
2. A feed forward neural network $f_{\boldsymbol{W}}(\boldsymbol{x})$ with L hidden layers, where each hidden layer $l \in \{1, ..., L\}$ has a weight matrix $\boldsymbol{W}_l \in \mathbb{R}^{D \times D}$ and a ReLU activation function. The output layer has a weight matrix $\boldsymbol{W}_{L+1} \in \mathbb{R}^{D \times 1}$ and no activation function.

In both models, there are no bias terms.

Your dataset $\mathcal{D}$ contains data points with nonnegative features $\boldsymbol{x}_n$ and the target y_n is continuous:

$$\mathcal{D} = \{\boldsymbol{x}_n, y_n\}_{n=1}^N \qquad \boldsymbol{x}_n \in \mathbb{R}_{\geq 0}^D, \quad y_n \in \mathbb{R}$$

Let $\boldsymbol{w}_{LS}^* \in \mathbb{R}^D$ be the optimal weights for the linear regression model corresponding to a *global* minimum of the following least squares optimization problem:

$$\boldsymbol{w}_{LS}^* = \arg\min_{\boldsymbol{w} \in \mathbb{R}^D} \mathcal{L}_{LS}(\boldsymbol{w}) = \arg\min_{\boldsymbol{w} \in \mathbb{R}^D} \frac{1}{2} \sum_{n=1}^N (\boldsymbol{w}^T \boldsymbol{x}_n - y_n)^2$$

Let $\boldsymbol{W}_{NN}^* = \{\boldsymbol{W}_1^*, \ldots, \boldsymbol{W}_{L+1}^*\}$ be the optimal weights for the neural network corresponding to a *global* minimum of the following optimization problem:

$$\boldsymbol{W}_{NN}^* = \arg\min_{\boldsymbol{W}} \mathcal{L}_{NN}(\boldsymbol{W}) = \arg\min_{\boldsymbol{W}} \frac{1}{2} \sum_{n=1}^N (f_{\boldsymbol{W}}(\boldsymbol{x}_n) - y_n)^2$$

a) Assume that the optimal $\boldsymbol{W}_{NN}^*$ you obtain are non-negative.
   What will the relation $(<, \leq, =, \geq, >)$ between the neural network loss $\mathcal{L}_{NN}(\boldsymbol{W}_{NN}^*)$ and the linear regression loss $\mathcal{L}_{LS}(\boldsymbol{w}_{LS}^*)$ be? Provide a mathematical argument to justify your answer.

Note that for any non-negative x and any non-negative W it holds $ReLU(xW) = xW$.

Therefore, since our data points have non-negative features x_i and the optimal weights W_{NN}^* are non-negative, every ReLU layer is equivalent to a linear layer when plugging in the optimal weights. This me [obscured]

$$ReLU(ReLU(x_i^T W_1^*)W_2^*)\cdots W_L^*)W_{L+1}^*$$
$$\cdots W_2^* \cdots W_{L+1}^*$$

where we defined $w_{NN}^* = W_1^* W_2^* \cdots W_{L+1}^*$. From this we can see that the neural network with optimal weights behaves like a linear regression with a different set of weights w_{NN}^*.

Note also that linear regression is a special case of the above neural network, i.e. for any weights w_{LS} you can find weights W_{NN} that produce the same output.

Given the above facts and since we the optimal weights correspond to a global minima we can conclude that $\mathcal{L}_{NN}(W_{NN}^*) = \mathcal{L}_{LS}(w_{LS}^*)$ and the optimal weights found by solving the least squares optimization problem will be $w_{LS}^* = w_{NN}^*$.

b) In contrast to (a), now assume that the optimal weights w_{LS}^* you obtain are non-negative. What will the relationship between the linear regression loss $\mathcal{L}_{LS}(w_{LS}^*)$ and the neural network loss $\mathcal{L}_{NN}(W_{NN}^*)$ be? Provide a mathematical argument to justify your answer.

As stated in (a) linear regression is a special case of the above neural network, i.e. for any weights w_{LS} you can find weights W_{NN} that produce the same output. That is, everything that can be learned with a linear regression can be learned equally well with a neural network.

However, the reverse direction doesn't hold, since in principle neural networks can learn more complicated functions compared to linear regression. Moreover, the given fact that w_{LS}^* are non-negative does not tell us anything about the optimal weights of the neural network W_{NN}^*.

Therefore it holds $\mathcal{L}_{NN}(W_{NN}^*) \leq \mathcal{L}_{LS}(w_{LS}^*)$ since the neural network can potentially find a better fit for the data (e.g. by taking advantage of non-linearity).

Problem 3: Load the notebook `exercise_08_notebook.ipynb` from Moodle. Fill in the missing code and run the notebook. Export (download) the evaluated notebook as PDF and add it to your submission.

Note: We suggest that you use Anaconda for installing Python and Jupyter, as well as for managing packages. We recommend that you use Python 3.

For more information on Jupyter notebooks, consult the Jupyter documentation. Instructions for converting the Jupyter notebooks to PDF are provided on Piazza.

The solution notebook is uploaded to Moodle.
